Problem Statement:

In a software application, if a user ends up forgetting the login password, a troublesome situation may not arise as the administrator of the software application may easily reset the password under certain situations. But what if the administrator forgets its own password? Will it be as easy as it was for a user?

Solution:

With the help of Full Stack Web Development, it allows us create a unique identification code that the administrator can use when the need arises to change the password.

Abstract:

It prompts the administrator to register online while purchasing the software for use. The information collected are stored in a local database which is encrypted and secure. After registration, a unique secret code is generated which is made available to the administrator, as well as stored in the same database. So, when the administrator seeks to change the password, the administrator is asked to provide the secret code and on successful verification provides the administrator with the ability to reset the password.
